

Ambiguous Cross Domain Hypothesis Generation with Citation Risk

Abstract. Cross domain hypothesis generation often combines partial signals from multiple disciplines. This creates a risk that a system may cite papers that exist but only weakly support the generated claim, or cite papers that cannot be found at all.

Keywords: hypothesis generation; citation risk; metadata matching; literature search; boundary cases

Introduction. The research problem is how to expose uncertain support and incorrect references during a live demonstration. This demo input is designed to be used with the workflow flag that injects one deliberately invalid citation, so the final verification table should include a Red row.

The goal is not to fabricate evidence. The invalid reference is explicitly labeled as a boundary case and should be rejected by the verifier.
